Mapping Object Role Modeling 2 Schemes into SROIQ (D) Description Logic

Heba M. Wagih, Doaa S. ElZanfaly, and Mohamed M. Kouta

Abstract—Ontology engineering is gaining a lot of focus due to the rapid technological development including the emergence of semantic web technology. The idea behind semantic Web is to create a web of data that can easily be shared, accessed and even transformed over a global scale independently of any application or domain. Descriptions logics achieve the goals of semantic web through providing a logical formalism for developed ontologies. SROIQ (D) represents the description logic underlying OWL2. In this paper we present the mapping rules from a rich graphical conceptual modeling technique called ORM2 to SROIQ (D).

Index Terms—ORM2, OWL2, semantic web, SROIQ (D)

I. INTRODUCTION

Semantic Web is the extension of the World Wide Web (WWW) that was invented by Tim Berners-Lee [1]. His vision was to allow data to be presented in a well defined structured form over the web. Berners-Lee defines the Semantic Web as “a web of data that can be processed directly and indirectly by machines”. One of the main forces behind the idea of semantic web technology is to facilitate data sharing and integration among different sources and applications. The two main pillars of Semantic web are how to integrate and exchange data from different heterogeneous sources and which language will be used in representing the data over the web. Ontology concept is considered the most promising basis for achieving the Semantic Web goals. A common agreed definition for ontology is a "formal, explicit specification of a shared conceptualization"[2]. In other words we can say that ontology is an approach used for achieving the semantic web goals by providing knowledge for a particular domain of interest over a wider scope in an organized form. Building any ontology is based on some concepts or components regardless the ontology language used.

In 2004, the World Wide Web Consortium (W3C) designed the web ontology language (OWL) and considered it as the standard for building ontologies [3]. OWL was built on the RDF however it provides more constructs for defining properties and classes. W3C introduced three variants of OWL, with different levels of expressiveness which are the OWL DL, OWL Lite and OWL Full. Later In October 2007, W3C working group extend OWL with new features and constraints and named the new OWL version by OWL2.

Five different sublanguages where introduced in OWL2 to provide different expressiveness levels which are OWL2DL, OWL2Full, OWL2EL, OWL2QL and OWL2RL. Descriptions logics (DL) [4, 5] present an essential step in defining, integrating, and maintaining ontologies. Developing high quality ontology is considered the most important goal of the semantic web that can be achieved by providing a logical formalism for ontologies using Descriptions logics. Semantic Web technology is heavily based on description logics. Knowledge in DL is classified into two parts which are the terminological components and the assertion components. Terminological components (T-Box) are used to represent classes and their properties while assertion component (A-Box) represents individuals and their properties. Different description logics were introduced as ALC, SHIQ, SHOIN, SHIF, SROIQ (D) and others. Since OWL2 is based on the description logic SROIQ (D) thus our study will focus on this type of description logic.

Conceptual modeling techniques represent one of the main data sources in building ontologies. Among the different modeling techniques the one we used in this paper is the ORM2. ORM2 is a powerful modeling technique characterized by its capability of representing most of the business constraints [6]. In this paper we propose an approach for mapping ORM2 to SROIQ description logic. In our approach we set a number of rules to facilitate the transformation of ORM2 schema to SROIQ (D) DL. All of the following diagrams are implemented using NORMA (Neumont ORM Architect) tool [7], which is an open source plug-in to Microsoft Visual Studio .NET. This paper is organized as follows: in Section 2 we discuss some of the literature related to our topic, a brief overview for ORM2 language and SROIQ (D) DL will be discussed in section 3 and in Section 4 we introduce the mapping mechanism from ORM2 to SROIQ (D) DL. In the last section, conclusions and future work are discussed.

II. RELATED WORK

Mapping description logics underpinning ontologies gained a lot of focus in the last few years. Many attempts were done to achieve a full mapping between different modeling techniques as ERD, UML and ORM to description logics.

In (2010) J. Ebert, T. Walter [8] proposed an approach to map between the conceptual modeling techniques UML (class diagrams) and OCL (object diagrams) and the description logic. The graph-based semantic description presented by the author in his research shows a high similarity between the concepts of modeling techniques and description logical models; however his mapping methodology lacks some constraints in the modeling ...
Object Role Modeling 2

Object Role Model (ORM) is a data modeling technique proposed by Terry Halpin in 1989 [14]. ORM has a rich graphical notation capability in representing many business techniques. ORM are characterized by being attribute-free proposed by Terry Halpin in 1989 [14]. ORM has a rich conceptual modeling technique and SROIQ description logic verbalization [15] which allows the participation into elementary ones. ORM consists of two main blocks diagrams. They simplify compound facts by breaking them which are: objects and relationship. Entities and attributes as well as n-ary facts. Also ORM supports the natural language verbalization [15] which allows the participation of end user in database development which is not provided of end user in database development which is not provided.

ORM2 added more expressivity and flexibility in representing business constraints. ORM2 substituted the English language symbols used in ORM with graphical symbols to improve the simplicity in the diagrams. It also introduced new constraints as role value constraint and objectified unaries.

B. Expressive Description Logic SROIQ (D)

Description logics (DLs) [4, 5] are the most effective knowledge representation formalism that provides a logical basis for presenting knowledge of a particular domain in an expressive well understood structure. Various description logics were proposed as DLR, DLRifd, SHOIN, SHOIQ and SROIQ. SROIQ [16] is the description logic underpinning the current web ontology language OWL2 as recommended by W3C.

SROIQ is the extension of the expressive SHOIN DL. Although SHOIN had proved its expressive power, however it lacks the ability of presenting some important business constraints as the qualified number restrictions. SROIQ presented some important rules that enrich the expressive capability of description logics with: Among these new rules are the disjoint roles where it permits the disjointness constraint between both classes and roles played by these classes. Also it introduced other important aspects as the negated role assertions and the reflexive and irreflexive roles. A full explanation for SROIQ description logic is presented in [16].

IV. MAPPING FRAMEWORK FROM ORM2 CONCEPTS TO SROIQ DESCRIPTION LOGIC

Description logics are used to provide a logical formalism for knowledge presented in any application domain specifically the semantic web applications. Integrating the relational databases supporting the Web applications into the Semantic Web requires mapping the associated schemas into equivalent description logic that underpin the ontology language used. The goal of this paper is to introduce an easy and understandable approach for mapping the ORM2 constructs to SROIQ DL syntax.

Table I presents the corresponding constructs between ORM2 and SROIQ. The set of mapping rules from ORM2 constructs to SROIQ are fully presented in the following subsections

A. Mapping Predicates from ORM2 to SROIQ

Roles played between two or more entity types are known as predicate. A predicate may be a unary type, binary, ternary or even n-ary predicate. SROIQ does not provide a mean to present the predicate in terms of Domain and Range constructs; however it can define two predicates inverse to each other as shown in Fig. 1.

B. Mapping Object Constraints from ORM2 to SROIQ

ORM2 has a number of constraints that is applied on its object types as value constraints and subtyping constraints. In the following subsections we will introduce these constraints together with their translation to SROIQ description logic.
TABLE I. CORRESPONDENCE BETWEEN SOME CONSTRUCTS OF ORM2 AND SROIQ.

1) **Value constraint**

Value constraints are value restrictions added to either the attached object type or the value type itself. Value constraints may be a list, enumeration of values, or a combination of lists and ranges. Value constraints imply stable values otherwise the schema will be continuously in changing state. Fig. 2 shows an example of mapping a value constraint added to entity type to SROIQ.

![Fig. 2. Mapping value constraint from ORM2 to SROIQ.](Image)

2) **Subtyping**

A class is considered a subtype of another class if the population in the subtype is subset of the population in the supertype. Different types of constraints are applied to subtyping as:

- **Exclusive (disjoint):** superclass instance may belong to at most one of the subclasses and the subclasses are disjoint. Exclusive constraint is mapped to SROIQ as shown in Fig. (3.a).
- **Inclusive-Or (total):** superclass instance belongs to at least one of the subclasses and is mapped to SROIQ as shown in Fig. (3.b).
- **Exclusive-Or (Partition):** superclass instance must belong to at most one of the subclasses and the subclasses are disjoint and is mapped to SROIQ as shown in Fig. (3.c).

C. **Mapping Role Constraints from ORM2 to SROIQ**

A number of constraints are applied to role facts as uniqueness, mandatory, set comparison, frequency, exclusion and ring constraints. In the following subsections we will introduce the mapping of these constraints to their equivalent SROIQ constructs.

1) **Internal uniqueness constraint (IUC)**

Internal uniqueness constraints are used to represent the one-to-one, one-to-many, and many-to-many relationships. Fig. 4 shows an example of mapping IUC to SROIQ DL.

![Fig. 4. Mapping 1:1 relationship from ORM2 to SROIQ.](Image)

2) **External uniqueness constraints**

No construct in SROIQ syntax is capable of translating the external uniqueness constraint in ORM.

3) **Mandatory constraints**

Mandatory constraint implies that each instance in the population must participate in the role fact. Mandatory constraint is mapped to SROIQ using a property restriction called existential quantification which states that each instance in a class is connected through a property to another instance in another class. Fig. 5 shows the mapping of mandatory constraint to SROIQ DL.

![Fig. 5. Mapping mandatory constraint from ORM2 to SROIQ.](Image)

4) **Set-comparison constraints**

Set-comparison constraints define how the population of one role (or a number of roles) related to another role (or a number of roles). There are three types of set-comparison constraint which are subset constraint, equality and exclusion constraint.

Subset_Constraint implies that for a certain business domain, the population of one role may be a subset of the population of second role. Subset constraint is applied to single roles as well as a sequence of roles. In Fig. 6 we show an example of mapping subset constraint applied to a sequence of roles in ORM2 to SROIQ.
Fig. 6. Mapping subset constraints from ORM2 to SROIQ.

TO map the subset constraint between single roles from ORM2 to SROIQ DL, we define the first role population as a subclass of the second role population as illustrated in Fig. 7.

\( \exists \text{Has first name. Name} \sqsubseteq \exists \text{Has family name. Name} \)

Fig. 7. Mapping subset constraints between single roles from ORM2 to SROIQ.

Equality Constraint implies that for a certain business domain, the population of one role must be equal to the population of the second role. Equality constraint can be substituted by two subset constraints in opposite directions. Mandatory constraint must be applied to the roles of the relation before using the equality constraints. If one role is mandatory and the other is optional, then equality constraints can not be applied. Fig. 8 shows an example of mapping equality constraint between a pair of roles to SROIQ.

\[ \text{Student} \sqsubseteq \neg(\exists \text{failed. Course Exam} \land \exists \text{Passed. Course Exam}) \]

Fig. 8. Mapping equality constraints from ORM2 to SROIQ.

Exclusion Constraint between single roles implies that an instance can participate in one role only. Fig. 9 shows the mapping of exclusion constraint between a pair of roles is mapped to SROIQ.

\[ \text{Dis (is Husband, is Parent)} \]

Fig. 9. Mapping exclusion constraint from ORM2 to SROIQ.

Mapping the exclusion constraint between single roles requires getting the complement of the intersection between these single roles as shown in Fig. 10.

\[ \text{Student} \sqsubseteq (\exists \text{failed. Course Exam} \lor \exists \text{Passed. Course Exam}) \]

Fig. 10. Mapping exclusion constraint between single roles from ORM2 to SROIQ.

5) **Inclusive or constraint**

Inclusive or Constraint (also known as disjunctive mandatory constraint) implies that an object instance must at least participate in one (possibly all) of the associated roles. Inclusive or Constraint is mapped to SROIQ as shown in Fig. 11.

\[ \text{Citizen} \equiv \exists \text{has. SSN} \sqcup \exists \text{got. Passport no} \]

Fig. 11. Mapping inclusive-or constraint from ORM2 to SROIQ.

6) **Exclusive-or constraint**

Exclusive or Constraint implies that an object instance must at least participate in one of the attached roles and that these fact type roles are disjoint. Exclusive or Constraint is a combined Inclusive-Or and Exclusion constraints. Fig. 12 shows the mapping of Exclusive or Constraint between fact type roles to SROIQ.

\[ \text{Dis (miss, attend)} \]

Fig. 12. Mapping exclusive or constraint between single roles from ORM2 to SROIQ.

7) **Frequency constraints**

Frequency constraint added to any role specifies the number of occurrences of this role by its object type. Frequency constraint is considered a generalized form of uniqueness constraints. Frequency constraints are either internal or external.

Internal Frequency Constraint is added to a single role or multiple roles in the same predicate. It is translated to SROIQ using the \((\geq, \leq)\) constructs as shown in Fig. 13.

\[ \text{Reviewer} \equiv \leq 4 \text{reviews. Publication} \]

Fig. 13. Mapping internal frequency constraint over single role from ORM2 to SROIQ.

External Frequency Constraint is applied to roles from two or more different predicates. No SROIQ constructs are available to map this constraint.

8) **Ring constraints**

Ring constraint is defined in [17] as “When two roles in a predicate are played by the same object type, the path from the object type through the role pair and back to the object type forms a ring”. A number of constraints can be applied to this ring. These constraints are:
Reflexive: relation on a set where an element can relate to itself. Fig. 14.(a) shows an example of mapping Reflexive constraint to SROIQ.

Irreflexive: relation on a set where no element is related to itself. Fig. 14.(b) shows an example of mapping Irreflexive constraint to SROIQ.

Symmetric: if and only if for each relationship instance, the inverse relationship also holds. Fig. 14.(c) shows an example of mapping Symmetric constraint to SROIQ.

Asymmetric: if a relationship holds then its inverse cannot hold. Fig. 14.(d) shows an example of mapping Asymmetric constraint to SROIQ.

Antisymmetric: if a relationship holds between non-identical objects then its inverse cannot hold.

Acyclic: no cycles of any length are allowed.

Intransitive: if a first object bears the relationship to a second, and the second bears the relationship to a third, then the first cannot bear the relationship to the third.

No available SROIQ constructs can directly map the acyclic and intransitive ring constraint; however both of these constraints are used together to represent the property chain feature in SROIQ. Property chain feature is mainly useful in some domains as in representing family relations. Property chain is used to restrict the population of certain isGrandParent properties where isGrandParent property will be derived from isParentOf property. Fig. 15 shows an example of mapping acyclic and intransitive ring constraint from ORM2 to SROIQ DL.

\[ P_1 \text{ isGrandParent of } P_2 \text{ (forward chain is allowed and is } \subseteq \text{)} \]

\[ P_1 \text{ isGrandParent of } P_2 \text{ (backward chain is allowed and is } \subseteq \text{)} \]

\[ P_1 \text{ isGrandParent of } P_2 \text{ (forward chain is allowed and is } \subseteq \text{)} \]

\[ P_1 \text{ isGrandParent of } P_2 \text{ (backward chain is allowed and is } \subseteq \text{)} \]

Fig. 14. Ring constraints in SROIQ.

Fig. 15. Mapping subproperty chain construct from ORM2 to SROIQ.

D. Mapping Objectification Constrains from ORM2 to SROIQ

Objectification is the process of transforming a relationship between objects into a new object thus it can be defined as a nested object type. Objectification process usually requires at least two roles with either single (1: n), spanning (m: n) or (1:1) uniqueness constraint as shown in Fig. 16. No available SROIQ constructs to map this constraint.

V. CONCLUSIONS AND FUTURE WORK

Ontology is Description logics present knowledge for any application domain in a logical formalism specifically for the semantic web applications. Among different DL languages, the one we used in our research is the SROIQ. SROIQ provides the solution for mapping most of the ORM2 constraints as ring constraints and disjoint role properties.

SROIQ still lacks the capability of mapping primary keys and n-ary relations where n > 2. Several attempts were presented to narrow the gap between ORM2 and DL languages mainly the DLRFd and SHOIN. In this paper we present a new approach to map between ORM2 to SROIQ description logic. Our research is considered the basis for implementing DL-based reasoning tools that supports knowledge acquisition through ORM2 modeling technique.

Our future work is mainly concerned in implementing a tool capable of mapping between ORM2 and SROIQ constructs.
